# A comparison of various estimation methods for ERGMs 

Mark S. Handcock<br>University of Washington<br>joint work with Krista J. Gile<br>Nuffield College, Oxford<br>Marijije van Duijn<br>Groningen, Netherlands<br>MURI-UCI April 24, 2009

For details, see:

- van Duijn, M. A. J., Gile, K. and Handcock, M.S. (2008). A Framework for the Comparison of Maximum Pseudo Likelihood and Maximum Likelihood Estimation of Exponential Family Random Graph Models. Social Networks, doi:10.1016/j.socnet.2008.10.0031

[^0]
## Statistical Models for Social Networks

Notation
A social network is defined as a set of $n$ social "actors" and a social relationship between each pair of actors.

$$
Y_{i j}= \begin{cases}1 & \text { relationship from actor } i \text { to actor } j \\ 0 & \text { otherwise }\end{cases}
$$

- call $Y \equiv\left[Y_{i j}\right]_{n \times n}$ a sociomatrix
- a $N=n(n-1)$ binary array
- The basic problem of stochastic modeling is to specify a distribution for $Y$ i.e., $P(Y=y)$

## A Framework for Network Modeling

Let $\mathcal{Y}$ be the sample space of $Y$ e.g. $\{0,1\}^{N}$
Any model-class for the multivariate distribution of $Y$ can be parametrized in the form:

$$
P_{\eta}(Y=y)=\frac{\exp \{\eta \cdot g(y)\}}{\kappa(\eta, \mathcal{Y})} \quad y \in \mathcal{Y}
$$

Besag (1974), Frank and Strauss (1986)

- $\eta \in \Lambda \subset R^{q} q$-vector of parameters
- $g(y) q$-vector of network statistics.
$\Rightarrow \quad g(Y)$ are jointly sufficient for the model
- For a "saturated" model-class $q=|\mathcal{Y}|-1 \quad$ e.g. $2^{N}-1$
- $\kappa(\eta, \mathcal{Y})$ distribution normalizing constant

$$
\kappa(\eta, \mathcal{Y})=\sum_{y \in \mathcal{Y}} \exp \{\eta \cdot g(y)\}
$$

A comparison of various estimation methods for ERGMs [3]

## Statistical Inference for $\eta$

Base inference on the loglikelihood function,

$$
\begin{gathered}
\ell(\eta)=\eta \cdot g\left(y_{\text {obs }}\right)-\log \kappa(\eta) \\
\kappa(\eta)=\sum_{\substack{\text { all possible } \\
\text { graphs } z}} \exp \{\eta \cdot g(z)\}
\end{gathered}
$$

## Approximating the loglikelihood

- Suppose $Y_{1}, Y_{2}, \ldots, Y_{m} \stackrel{\text { i.i.d. }}{\sim} P_{\eta_{0}}(Y=y)$ for some $\eta_{0}$.
- Using the LOLN, the difference in log-likelihoods is

$$
\begin{aligned}
\ell(\eta)-\ell\left(\eta_{0}\right) & =\log \frac{\kappa\left(\eta_{0}\right)}{\kappa(\eta)} \\
& =\log \mathbf{E}_{\eta_{0}}\left(\exp \left\{\left(\eta_{0}-\eta\right) \cdot g(Y)\right\}\right) \\
& \approx \log \frac{1}{M} \sum_{i=1}^{M} \exp \left\{\left(\eta_{0}-\eta\right) \cdot\left(g\left(Y_{i}\right)-g\left(y_{\mathrm{obs}}\right)\right)\right\} \\
& \equiv \tilde{\ell}(\eta)-\tilde{\ell}\left(\eta_{0}\right)
\end{aligned}
$$

- Simulate $Y_{1}, Y_{2}, \ldots, Y_{m}$ using a MCMC (Metropolis-Hastings) algorithm
$\Rightarrow$ Snijders (2002); Handcock (2002).
- Approximate the MLE $\hat{\eta}=\operatorname{argmax}_{\eta}\left\{\tilde{\ell}(\eta)-\tilde{\ell}\left(\eta_{0}\right)\right\}$ (MC-MLE)
$\Rightarrow$ Geyer and Thompson (1992)
- Given a random sample of networks from $P_{\eta_{0}}$, we can thus approximate (and subsequently maximize) the loglikelihood shifted by a constant.

## Conditional log-odds of an edge

Notation: For a network $y$ and a pair $(i, j)$ of nodes,

- $y_{i j}=0$ or 1 , depending on whether there is an edge
- $y_{i j}^{c}$ denotes the status of all pairs in $y$ other than $(i, j)$
- $y_{i j}^{+}$denotes the same network as $y$ but with $y_{i j}=1$
- $y_{i j}^{-}$denotes the same network as $y$ but with $y_{i j}=0$

## Conditional log-odds of an edge

Notation: For a network $y$ and a pair $(i, j)$ of nodes,

- $y_{i j}=0$ or 1 , depending on whether there is an edge
- $y_{i j}^{c}$ denotes the status of all pairs in $y$ other than $(i, j)$
- $y_{i j}^{+}$denotes the same network as $y$ but with $y_{i j}=1$
- $y_{i j}^{-}$denotes the same network as $y$ but with $y_{i j}=0$

Conditional on $Y_{i j}^{c}=y_{i j}^{c}, Y$ has only two possible states, depending on whether $Y_{i j}=0$ or $Y_{i j}=1$.

## Conditional log-odds of an edge

## Notation: For a network $y$ and a pair $(i, j)$ of nodes,

- $y_{i j}=0$ or 1 , depending on whether there is an edge
- $y_{i j}^{c}$ denotes the status of all pairs in $y$ other than $(i, j)$
- $y_{i j}^{+}$denotes the same network as $y$ but with $y_{i j}=1$
- $y_{i j}^{-}$denotes the same network as $y$ but with $y_{i j}=0$

Conditional on $Y_{i j}^{c}=y_{i j}^{c}, Y$ has only two possible states, depending on whether $Y_{i j}=0$ or $Y_{i j}=1$.
Let's calculate the ratio of the two respective probabilities.
[We'll use $P_{\theta}(Y=y)=\exp \left\{\theta^{t} g(y)\right\} / \kappa(\theta)$.]

## Conditional log-odds of an edge

Notation: For a network $y$ and a pair $(i, j)$ of nodes,

- $y_{i j}=0$ or 1 , depending on whether there is an edge
- $y_{i j}^{c}$ denotes the status of all pairs in $y$ other than $(i, j)$
- $y_{i j}^{+}$denotes the same network as $y$ but with $y_{i j}=1$
- $y_{i j}^{-}$denotes the same network as $y$ but with $y_{i j}=0$

$$
\frac{P\left(Y_{i j}=1 \mid Y_{i j}^{c}=y_{i j}^{c}\right)}{P\left(Y_{i j}=0 \mid Y_{i j}^{C}=y_{i j}^{C}\right)}=\frac{\exp \left\{\theta^{t} g\left(y_{i j}^{+}\right)\right\}}{\exp \left\{\theta^{t} g\left(y_{i j}^{-}\right)\right\}}
$$

A lot of cancellation happened on the right hand side!

## Conditional log-odds of an edge

Notation: For a network $y$ and a pair $(i, j)$ of nodes,

- $y_{i j}=0$ or 1 , depending on whether there is an edge
- $y_{i j}^{c}$ denotes the status of all pairs in $y$ other than $(i, j)$
- $y_{i j}^{+}$denotes the same network as $y$ but with $y_{i j}=1$
- $y_{i j}^{-}$denotes the same network as $y$ but with $y_{i j}=0$

$$
\frac{P\left(Y_{i j}=1 \mid Y_{i j}^{C}=y_{i j}^{c}\right)}{P\left(Y_{i j}=0 \mid Y_{i j}^{C}=y_{i j}^{C}\right)}=\exp \left\{\theta^{t}\left[g\left(y_{i j}^{+}\right)-g\left(y_{i j}^{-}\right)\right]\right\}
$$

A lot of cancellation happened on the right hand side!

## Conditional log-odds of an edge

Notation: For a network $y$ and a pair $(i, j)$ of nodes,

- $y_{i j}=0$ or 1 , depending on whether there is an edge
- $y_{i j}^{c}$ denotes the status of all pairs in $y$ other than $(i, j)$
- $y_{i j}^{+}$denotes the same network as $y$ but with $y_{i j}=1$
- $y_{i j}^{-}$denotes the same network as $y$ but with $y_{i j}=0$

$$
\log \frac{P\left(Y_{i j}=1 \mid Y_{i j}^{c}=y_{i j}^{c}\right)}{P\left(Y_{i j}=0 \mid Y_{i j}^{C}=y_{i j}^{C}\right)}=\quad \theta^{t}\left[g\left(y_{i j}^{+}\right)-g\left(y_{i j}^{-}\right)\right]
$$

## Conditional log-odds of an edge

Notation: For a network $y$ and a pair $(i, j)$ of nodes,

- $\Delta(g(y))_{i j}$ denotes the vector of change statistics,

$$
\Delta(g(y))_{i j}=g\left(y_{i j}^{+}\right)-g\left(y_{i j}^{-}\right) .
$$

So $\Delta(g(y))_{i j}$ is the conditional log-odds of edge $(i, j)$.

$$
\log \frac{P\left(Y_{i j}=1 \mid Y_{i j}^{c}=y_{i j}^{C}\right)}{P\left(Y_{i j}=0 \mid Y_{i j}^{C}=y_{i j}^{C}\right)}=\quad \theta^{t} \Delta(g(y))_{i j}
$$

## Simulating random networks

## Goal:

Simulate random network(s) $Y$ from an ERGM.
Note: There is no model, only a model class, unless we have a specific parameter vector $\theta$; we'll need to fix an $\theta$ somehow.

## Simulating random networks

## Goal:

Simulate random network(s) $Y$ from an ERGM.
Note: There is no model, only a model class, unless we have a specific parameter vector $\theta$; we'll need to fix an $\theta$ somehow.

We'll discuss one way to achieve the goal, called a Metropolis algorithm.

The Metropolis algorithm is one of a broad class of algorithms called Markov Chain Monte Carlo (MCMC) algorithms.

## Obtaining samples via Markov Chain Monte Carlo

Whence the name MCMC?

- Markov Chain: A sequence $Y_{1}, Y_{2}, \ldots$ where the $(i+1)$ th network is randomly generated based on the ith network.
- Monte Carlo: The computational implementation of the "randomly generated" part.

## MCMC Idea for simulating networks:

Simulate a carefully designed Markov chain on the sample space of networks for a while. When we stop it, we'll have our random network.

## Metropolis algorithm

- First, select a pair of nodes at random, say $(i, j)$.

## Metropolis algorithm

- First, select a pair of nodes at random, say $(i, j)$.
- Calculate the ratio

$$
\begin{aligned}
\pi & =\frac{P\left(Y_{i j} \text { changes } \mid Y_{i j}^{c}=y_{i j}^{c}\right)}{P\left(Y_{i j} \text { does not change } \mid Y_{i j}^{C}=y_{i j}^{C}\right)} \\
& =\exp \left\{ \pm \theta_{0}^{t} \Delta(g(y))_{i j}\right\}
\end{aligned}
$$

## Metropolis algorithm

- First, select a pair of nodes at random, say $(i, j)$.
- Calculate the ratio

$$
\begin{aligned}
\pi & =\frac{P\left(Y_{i j} \text { changes } \mid Y_{i j}^{c}=y_{i j}^{c}\right)}{P\left(Y_{i j} \text { does not change } \mid Y_{i j}^{c}=y_{i j}^{c}\right)} \\
& =\exp \left\{ \pm \theta_{0}^{t} \Delta(g(y))_{i j}\right\}
\end{aligned}
$$

- Accept the change of $Y_{i j}$ with probability $\min \{1, \pi\}$ (i.e., always make the change if $\pi \geq 1$; otherwise, only make the change sometimes).

## Metropolis algorithm

- First, select a pair of nodes at random, say $(i, j)$.
- Calculate the ratio

$$
\begin{aligned}
\pi & =\frac{P\left(Y_{i j} \text { changes } \mid Y_{i j}^{c}=y_{i j}^{c}\right)}{P\left(Y_{i j} \text { does not change } \mid Y_{i j}^{c}=y_{i j}^{C}\right)} \\
& =\exp \left\{ \pm \theta_{0}^{t} \Delta(g(y))_{i j}\right\}
\end{aligned}
$$

- Accept the change of $Y_{i j}$ with probability $\min \{1, \pi\}$ (i.e., always make the change if $\pi \geq 1$; otherwise, only make the change sometimes).

Note: The values of $g\left(y_{i j}^{+}\right)$and $g\left(y_{i j}^{-}\right)$are never needed; only the difference $\Delta(g(y))_{i j}$ matters.

## How should $\theta_{0}$ be chosen?

- Theoretically, the estimated value of $\ell(\theta)-\ell\left(\theta_{0}\right)$ converges to the true value as the size of the MCMC sample increases, regardless of the value of $\theta_{0}$.

## How should $\theta_{0}$ be chosen?

- Theoretically, the estimated value of $\ell(\theta)-\ell\left(\theta_{0}\right)$ converges to the true value as the size of the MCMC sample increases, regardless of the value of $\theta_{0}$.
- However, in practice this convergence can be agonizingly slow, especially if $\theta_{0}$ is not chosen close to the maximizer of the likelihood.

## How should $\theta_{0}$ be chosen?

- Theoretically, the estimated value of $\ell(\theta)-\ell\left(\theta_{0}\right)$ converges to the true value as the size of the MCMC sample increases, regardless of the value of $\theta_{0}$.
- However, in practice this convergence can be agonizingly slow, especially if $\theta_{0}$ is not chosen close to the maximizer of the likelihood.
- A choice that sometimes works is the MPLE (maximum pseudolikelihood estimate)

## Outline

## (1) Maximum likelihood estimation

(2) Approximating the MLE
(3) Simulating random networks via MCMC
(4) Maximum pseudolikelihood
(5) Goodness of fit

## Maximum Pseudolikelihood: Intuition

- What if we assume that there is no dependence (or very weak dependence) among the $Y_{i j}$ ?

## Maximum Pseudolikelihood: Intuition

- What if we assume that there is no dependence (or very weak dependence) among the $Y_{i j}$ ?
- In other words, what if we approximate the marginal $P\left(Y_{i j}=1\right)$ by the conditional $P\left(Y_{i j}=1 \mid Y_{i j}^{C}=y_{i j}^{C}\right)$ ?

## Maximum Pseudolikelihood: Intuition

- What if we assume that there is no dependence (or very weak dependence) among the $Y_{i j}$ ?
- In other words, what if we approximate the marginal $P\left(Y_{i j}=1\right)$ by the conditional $P\left(Y_{i j}=1 \mid Y_{i j}^{C}=y_{i j}^{C}\right)$ ?
- Then the $Y_{i j}$ are independent with

$$
\log \frac{P\left(Y_{i j}=1\right)}{P\left(Y_{i j}=0\right)}=\theta^{t} \Delta\left(g\left(y^{\mathrm{obs}}\right)\right)_{i j}
$$

so we obtain an estimate of $\theta$ using straightforward logistic regression.

## Maximum Pseudolikelihood: Intuition

- What if we assume that there is no dependence (or very weak dependence) among the $Y_{i j}$ ?
- In other words, what if we approximate the marginal $P\left(Y_{i j}=1\right)$ by the conditional $P\left(Y_{i j}=1 \mid Y_{i j}^{C}=y_{i j}^{C}\right)$ ?
- Then the $Y_{i j}$ are independent with

$$
\log \frac{P\left(Y_{i j}=1\right)}{P\left(Y_{i j}=0\right)}=\theta^{t} \Delta\left(g\left(y^{\mathrm{obs}}\right)\right)_{i j}
$$

so we obtain an estimate of $\theta$ using straightforward logistic regression.

- Result: The maximum pseudolikelihood estimate.

## Maximum Pseudolikelihood: Intuition

- What if we assume that there is no dependence (or very weak dependence) among the $Y_{i j}$ ?
- In other words, what if we approximate the marginal $P\left(Y_{i j}=1\right)$ by the conditional $P\left(Y_{i j}=1 \mid Y_{i j}^{c}=y_{i j}^{c}\right)$ ?
- Then the $Y_{i j}$ are independent with

$$
\log \frac{P\left(Y_{i j}=1\right)}{P\left(Y_{i j}=0\right)}=\theta^{t} \Delta\left(g\left(y^{\mathrm{obs}}\right)\right)_{i j}
$$

so we obtain an estimate of $\theta$ using straightforward logistic regression.

- Result: The maximum pseudolikelihood estimate.
- For independence models, MPLE $=$ MLE

## Warnings about MPLE

Unfortunately, little is known about the quality of MPL estimates in general, but we do know some ways in which they can be misleading.

- If the model is bad, you'll get nice-looking MPLE results that do not reveal the problem.
- If the model is good, in many cases the MPLE looks "close" to the MLE; however, "close" can be deceiving, since small changes in $\theta$ can sometimes lead to large differences in the behavior of randomly generated networks.

## Geometry of Exponential Random Graph Models

Consider the alternative parametrization of the models $\mu: \Lambda \rightarrow \operatorname{int}(\mathrm{C})$ defined by

$$
\mu(\eta)=\mathbf{E}_{\eta}[Z(Y)] \equiv \sum_{y \in \mathcal{Y}} Z(y) \frac{\exp \left\{\eta^{T} Z(y)\right\}}{c(\eta)}
$$

- The mapping is injective:

$$
\mu\left(\eta_{a}\right)=\mu\left(\eta_{b}\right) \rightarrow P_{\eta_{a}}(Y=y)=P_{\eta_{b}}(Y=y) \forall y
$$

- The mapping in strictly increasing in the sense that

$$
\left(\eta_{a}-\eta_{b}\right)^{T}\left(\mu\left(\eta_{a}\right)-\mu\left(\eta_{b}\right)\right) \geq 0
$$

with equality only if $P_{\eta_{a}}(Y=y)=P_{\eta_{b}}(Y=y) \forall y$.

- Represents an alternative parameterization of the model

## Example of the 2-star model

$$
P(Y=y)=\frac{\exp \left\{\eta_{1} E(y)+\eta_{2} S(y)\right\}}{c\left(\eta_{1}, \eta_{2}\right)} \quad y \in \mathcal{Y}
$$

where $E(y)$ is the number of edges $\left(0-N=\binom{g}{2}\right.$ )
$S(y)$ is the number of $2-\operatorname{stars}\left(0-M=3\binom{g}{3}\right)$

$$
\mu_{1}=\mathbf{E}_{\eta}[E(Y)]=\sum_{i<j} \mathbf{E}\left[Y_{i j}\right]=N \mathbf{E}\left[Y_{12}\right]
$$

- $\mu_{1}$ is the expected number of edges, or $\frac{1}{N} \mu_{1}$ is the probability that two actors are linked.

$$
\mu_{2}=\mathbf{E}_{\eta}[S(Y)]=\sum_{i<j<k} \mathbf{E}\left[Y_{i j} Y_{i k}\right]=M \mathbf{E}\left[Y_{12} Y_{13}\right]
$$

- $\mu_{2}$ is the expected number of $2-$ stars, or
$\frac{1}{M} \mu_{2}$ is the probability that a given actor is tied to two randomly chosen other actors.

Figure 4: Regions of the parameter space of $\mu$

Figure 5: Regions of the parameter space of $\theta$

## In some cases mixed parameterizations may be better

Let $\left(t^{(1)}, t^{(2)}\right)$ be a partition of $t$ such that:
$-t^{(1)}$ is interpretable as a mean value parametrization
$-t^{(2)}$ is interpretable as the "natural" conditional log-odds
Consider similar partitions $\left(\eta^{(1)}, \eta^{(2)}\right)$ of $\eta$ and $\left(\mu^{(1)}(\eta), \mu^{(2)}(\eta)\right)$ of $\mu(\eta)$.
Let $\Lambda^{(2)}$ be the set of values of $\eta^{(2)}$ for $\eta$ varying in $\Lambda$ and $C^{(1)}$ be the convex hull of $\left\{t^{(1)}(y): y \in \mathcal{Y}\right\}$.

The mapping $\eta: \Lambda \rightarrow \Lambda^{(2)} \times \operatorname{int}\left(\mathrm{C}^{(1)}\right)$ defined by

$$
\begin{equation*}
\eta(\eta)=\left(\mu^{(1)}(\eta), \eta^{(2)}\right) \tag{1}
\end{equation*}
$$

is a mixed parametrization of the model $(\mathcal{Y}, t, \eta)$.
The components $\mu^{(1)}$ and $\eta^{(2)}$ are variationally independent, that is, the range of $\eta(\eta)$ is a product space.

## Degeneracy in the mean value parametrization

- Definition: A model is near degenerate if $\mu(\eta)$ is close to the boundary of $C$

Let $\operatorname{deg} \mathcal{Y}=\{y \in \mathcal{Y}: Z(y) \in \operatorname{bdC}\}$ be the set of graph on the boundary of the convex hull.
idea: Based on the geometry of the mean value parametrization the expected sufficient statistics are close to a boundary of the hull and the model will place much probability mass on graphs in $\operatorname{deg} \mathcal{Y}$.

Figure 4: Regions of the parameter space of $\mu$

This statement can be quantified in a number of ways:
Result: Let $e$ be a unit vector in $\mathbf{R}^{q}$ and $\mathrm{bd}(e)=\sup _{\mu \in \operatorname{intC}}\left(e^{T} \mu\right)$.

1. $\mu(\lambda e) \rightarrow \operatorname{bd}(e) e$ as $\lambda \uparrow \infty$.
2. $P_{\lambda e, \mathcal{Y}}(Y \in \operatorname{deg} \mathcal{Y}) \rightarrow 1$ as $\lambda \uparrow \infty$.
3. For every $d<\operatorname{bd}(e), P_{\lambda e, y}\left(e^{T} Z(Y) \leq d\right) \rightarrow 0$ as $\lambda \uparrow \infty$.
4. Let $\eta_{0} \in \operatorname{intC}$.

Then Kullback - Leibler divergence $\left(\eta_{0} ; \lambda e\right) \rightarrow \infty$ as $\lambda \uparrow \infty$.

## Effect of Near-Degeneracy on MCMC Estimation

- Closely related to nice properties of simple MCMC schemes (Geyer 1999).
- If a random graph model is simulated using a MCMC based on a near-degenerate $\psi$ it will very likely fail.
- Full-conditional MCMC with dyad update:

$$
M(\psi)=\max _{y \in \mathcal{Y}}\left|\psi^{T} \delta\left(y_{i j}^{c}\right)\right|
$$

where $\delta\left(y_{i j}^{c}\right)=Z\left(y_{i j}^{+}\right)-Z\left(y_{i j}^{-}\right)$

- As $\mu(\psi) \rightarrow \operatorname{bd}(\mathrm{C}), M(\psi) \rightarrow \infty$
- There exists $y \in \mathcal{Y}$ with

$$
\text { logit }\left[P\left(Y_{i j}=1 \mid Y_{i j}^{c}=y_{i j}^{c}\right)\right]= \pm M(\psi)
$$

- If $\psi$ is near-degenerate then $M(\psi)$ is large and the MCMC will mix very slowly.

## Example of degeneracy of the 2-star model

$$
P(Y=y)=\frac{\exp \left\{\eta_{1} E(y)+\eta_{2} S(y)\right\}}{c\left(\eta_{1}, \eta_{2}\right)} \quad y \in \mathcal{Y}
$$

- $M(\eta)=\max \left\{\left|\eta_{1}\right|, \eta_{1}+2(g-2) \eta_{2}\right\}$ MCMC will usually mix poorly.
- If $\mu(\eta)$ close to $(3,0)$ (e.g., $\eta=(4.5,-18.4)$ ) then $M(\eta)=4.5$

So an MCMC will approach $(3,0)$ and stay there ( $98.9 \%$ and $1.1 \%$ at $(2,0) \in \operatorname{bd}(C)$ ).

- If $\mu(\eta)$ close to $(9,40)$ (e.g., $\eta=(-3.43,0.683)$ ) then $M(\eta)=3.43$. The model places $50 \%$ of its mass on graphs with 2 or fewer edges and $36 \%$ on graphs with at least 19 edges.
- The model is also unstable e.g., $\eta=(-3.43,0.67)$ ) $\mu(\eta) \approx(4.4,17.1)$ and the model places almost all its mass on empty graphs.

Figure 4: Regions of the parameter space of $\mu$

## Estimation within the mean value parametrization

- If $Z\left(y_{o b s}\right) \in \operatorname{int}(\mathrm{C})$, the MLE of $\mu$ is $Z\left(y_{o b s}\right)$.
- If $Z\left(y_{o b s}\right) \notin \operatorname{int}(\mathrm{C})$ the MLE of $\mu$ does not exist.
- The MLE $\hat{\mu}$ is unbiased and has minimum variance:

$$
\begin{gathered}
\mathbf{E}_{\eta}(\hat{\mu})=\mathbf{E}_{\eta}[Z(Y)]=\mu(\eta)=\left[\frac{\partial \log c(\eta)}{\partial \eta_{i}}\right](\eta) \\
\mathbf{V}_{\eta}(\hat{\mu})=\mathbf{V}_{\eta}[Z(Y)]=\left[\frac{\partial^{2} \log c(\eta)}{\partial \eta_{i} \partial \eta_{j}}\right]
\end{gathered}
$$

- An estimate of the variance-covariance is available using the same MCMC.

Figure 4: Regions of the parameter space of $\mu$

## Existence and uniqueness of MLE

Let $C$ be the convex hull of $\{Z(y): y \in \mathcal{Y}\}$

- the convex hull of the discrete support points.

Let $\operatorname{int}(\mathrm{C})$ be the interior of $C$.

Result (Barndorff-Nielsen 1978)
The MLE exists if, and only if, $Z\left(y_{\text {observed }}\right) \in \operatorname{int}(\mathrm{C})$ If it exists, it is unique and can be found by solving the likelihood equations or by direct optimization of $\mathcal{L}$.

Figure 1: Enumeration of sufficient statistics for graphs with 7 nodes. The circles are centered on the possible values and the area of the circle is proportional to the number of graphs with that value of the sufficient statistic. There are a total of 2,097,152 graphs.

## A Bias-corrected Pseudo-likelihood Estimator

The penalized pseudo-likelihood

$$
\begin{equation*}
\ell_{B P}(\eta ; y) \equiv \ell_{P}(\eta ; y)+\frac{1}{2} \log |I(\eta)| \tag{2}
\end{equation*}
$$

where $I(\eta)$ denotes the expected Fisher information matrix for the formal logistic model underlying the pseudo-likelihood evaluated at $\eta$.

Motivated by Firth (1993) as a general approach to reducing the asymptotic bias of MLEs

We refer to the estimator that maximizes $\ell_{B P}\left(\eta ; y_{o b s}\right)$ as the maximum bias-corrected pseudo-likelihood estimator (MBLE).

## Simulation study of MLE, MPLE and MBLE

The general structure of the simulation study is as follows:

- Begin with the MLE model fit of interest for a given network.
- Simulate networks from this model fit.
- Fit the model to each sampled network using each method under comparison.
- Evaluate the performance of each estimation procedure in recovering the known true parameter values, along with appropriate measures of uncertainty.

## Introduction to Law Firm Collaboration Example

From the Emmanuel Lazega's study of a Corporate Law Firm:

- Each partner asked to identify the others with whom (s)he collaborated.
- Seniority, Sex, Practice (corporate or litigation) and Office (3 locations) available for all 36 partners.

Table 1: Natural and mean value model parameters for Original model for Lazega data, and for model with increased transitivity.

| Parameter | Natural Parameterization | Mean Value Parameterization |  |  |
| :--- | :---: | :---: | :---: | :---: |
|  | Original | Increased <br> Transitivity | Original | Increased <br> Transitivity |
| Structural |  |  |  |  |
| edges | -6.506 | -6.962 | 115.00 | 115.00 |
| GWESP | 0.897 | 1.210 | 190.31 | 203.79 |
| Nodal |  |  |  |  |
| seniority | 0.853 | 0.779 | 130.19 | 130.19 |
| practice | 0.410 | 0.346 | 129.00 | 129.00 |
| Homophily |  |  |  |  |
| practice | 0.759 | 0.756 | 72.00 | 72.00 |
| gender | 0.702 | 0.662 | 99.00 | 99.00 |
| office | 1.145 | 1.081 | 85.00 | 85.00 |

Figure 1: Boxplots of the distribution of the MLE, the MPLE and the MBLE of the geometrically weighted edgewise shared partner statistic (GWESP), differential activity by practice statistic (Nodal), and homophily on practice statistic (Homophily) under the natural and mean value parameterization for 1000 samples of the original Lazega network and 1000 samples of the Lazega network with increased transitivity
(a)

Natural Parameterization, GWESP

(b)

Mean Value Parameterization, GWESP

Table 2: Relative efficiency of the MPLE, and the MBLE with respect to the MLE

| Natural Parameterization |  | Mean Value Parameterization |  |

## Summary

This is a framework to assess estimators for (ERG) models.
Key features:

- The use of the mean-value parametrization space as an alternate metric space to assess model fit.
- The adaptation of a simulation study to the specific circumstances of interest to the researcher: e.g. network size, composition, dependency structure.
- It assesses the efficiency of point estimation via mean-squared error in the different parameter spaces.
- It assesses the performance of measures of uncertainty and hypothesis testing via actual and nominal interval coverage rates.
- It provides methodology to modify the dependence structure of a model in a known way, for example, changing one aspect while holding the other aspects fixed.
- It enables the assessment of performance of estimators to be to alternative specifications of the underlying model.

## Case study:

- MLE superior to MPLE and MBLE for structural and covariate effects.
- due to the dependence between the GWESP estimates and others
- Greater variability in the GWESP results translates to broad Cl
- GWESP standard errors are underestimated resulting in too narrow CI
- Inference based on the MPLE is suspect
- Tests for structural parameters tend to be liberal
- Tests for nodal and dyadic attributes conservative
- MLE drastically superior on the mean value scale ( $30 \%$ of MSE of MP(B)LE)
- MPLE nominal $95 \% \mathrm{Cl}$ coverage is $50 \%$.
- Gets worse as dependence increases.
- MBLE
- Smallest bias for the natural parameter estimates.
- MBLE consistently out-performs the MPLE (for both natural and mean-value parameters)
