The Memory Hierarchy

• The trade-off of size and speed

- Problem: datasets too big to fit in memory
- External-Memory Model: manage disk/memory transfers manually! [Vitter]
- Parameters:
 - M memory capacity
 - N − # stored items
 - D # disks
 - B block size
- We measure the number of I/O's between disks and memory

Key bounds:

•
$$scan(N) = \theta(\frac{N}{DB})$$

• $sort(N) = \theta(\frac{\overline{N}}{DB} \log_{M/B} \frac{N}{B})$

Graph Sparsity

k-core

maximal connected subgraph with all vertices having degree $\geq k$

k-core number

maximal k s.t. graph has a k-core

degeneracy

graph has degeneracy d, if d is the smallest number s.t. every subgraph has a vertex of degree $\leq d$

Fact

Graph has degeneracy d iff its k-core number is equal to d. We call such graph d-degenerate

External-Memory Case: Analysis

- Computes a (2 + ε)d-degeneracy ordering of a d-degenerate graph
- Does not require prior knowledge of d
- O(lg n) while iterations
- O(sort(dn)) overall I/O complexity

Finding Cycles of Given Length

Cycles of Given Length

- Problem: find a cycle of length c in graph G
- NP-complete in general case, feasible for small c
- Our algorithm external-memory adaptation of a sequential algorithm [Alon *et al. (2009)*]

All Maximal Cliques

All Maximal Cliques

- Problem: given graph *G*, list all its maximal cliques
- Basic version of the algorithm [Bron and Kerbosch (1973)]: recursive search maintaining the following sets:
 - R current clique (possibly non-maximal)
 - P vertices to be considered for adding to clique
 - X forbidden vertices (not to be added to clique)
- Further improved [Tomita et al. (2006)]

- [Eppstein *et al. (2010)]*: Run the improved version of the algorithm with initial values:
 - R vertex v
 - P later neighbors of v in degeneracy ordering
 - X earlier neighbors of v in degeneracy ordering

(for every v)

- [Eppstein *et al. (2010)]*: Run the improved version of the algorithm with initial values:
 - R vertex v
 - P later neighbors of v in degeneracy ordering
 - X earlier neighbors of v in degeneracy ordering

(for every v)

• Runs in $O(3^{d/3}dn)$ time

- [Eppstein *et al. (2010)]*: Run the improved version of the algorithm with initial values:
 - R vertex v
 - P later neighbors of v in degeneracy ordering
 - X earlier neighbors of v in degeneracy ordering

(for every v)

- Runs in O(3^{d/3}dn) time
- Our external-memory version of this algorithm:
 O(3^{δ/3}sort(δn)) I/O's (δ = (2 + ε)d)

- Existing sequential algorithms utilizing degeneracy ordering can be adapted into the external-memory model

Betweenness Centrality

The betweenes of a vertex v in a graph G: = (V,E) with V vertices is defined as follows:

 For each pair of vertices (s,t), consider the shortest paths between them.

For each pair of vertices (s,t),
 determine the fraction of shortest
 paths that pass through the vertex in
 question (here, vertex v).

3. Sum this fraction over all pairs of vertices (s,t).
